

The following graph, depicting the foreign-born (immigrant) population in the United States (US) from 1850 to 2010, best supports which of the following conclusions?

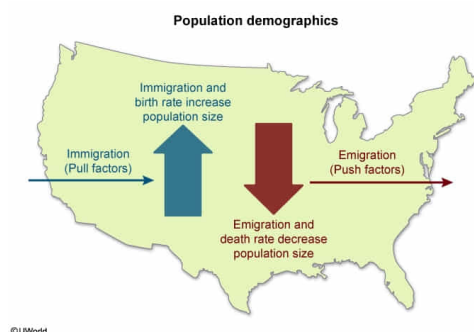

- ☐ A. Compared to 1910, there was a decrease in pull factors driving immigration to the US in 2010 [21%]
- ✓ ☒ B. From 1910 to 1930, the fertility rate of the US population exceeded that of the immigration rate [48%]
- ☐ C. From 1940 to 1970, the mortality rate of the US foreign-born population declined [7%]
- ☐ D. From 1980 to 2010, the foreign-born fertility rate exceeded the native-born fertility rate [21%]

Correct

49% answered correctly

Explanation:

Immigration is the **relocation** of individuals **into** an area, whereas **emigration** is **relocation out** of an area. People tend to *emigrate from* less developed/poorer countries, *immigrating to* more developed/wealthier ones. **Push factors** (eg, unemployment, war) in the country of origin **drive emigration**, whereas **pull factors** (eg, job opportunities) in the receiving country **attract** people to **immigrate**.

The size and demographic makeup of a population is determined by immigration/emigration rates, fertility (birth) rates, and mortality (death) rates. **Fertility** rates measure **population increases** due to **births**, whereas **mortality** rates measure **population declines** due to **deaths**.

This graph displays the number of immigrants and the percentage of the total US population composed of immigrants from 1850 to 2010. From 1910 to 1930, the number of immigrants (graph bars) increased,

whereas the percentage of immigrants in the overall US population (graph line) decreased, which would occur only if the native-born population increased faster than the foreign-born (immigrant) population. A fertility rate exceeding the immigration rate would produce this outcome.

(Choice A) The graph does not provide information about either push or pull factors that influenced immigration to the US.

(Choice C) From 1940 to 1970, there was a steady decline in the foreign-born percentage of the

population, suggesting that the mortality rate of the foreign-born population may have *increased* (not decreased).

(Choice D) From 1980 to 2010, the number and percentage of foreign-born in the population increased. Whether the parents are foreign-born or native-born, children born in the US are native-born, so it is not possible to determine from this graph whether the foreign-born fertility rate exceeded the native-born fertility rate.

Educational objective:

Migration patterns track the movement of people from one country to another. People tend to emigrate from (leave) poorer countries and immigrate (relocate) to wealthier countries. Push factors (eg, war) drive emigration, whereas pull factors (eg, economic opportunity) drive immigration. Migration, fertility (birth) rate, and mortality (death) rate impact the size and demographics of a population.
