

Compared to women's social networks, men's social networks tend to be larger, have more weak ties, and provide more information about work-related topics; therefore, men's social networks most likely confer:

- ☐ A. less social capital and less social mobility. [1%]
- ✓ ☒ B. more social capital and more social mobility. [41%]
- ☐ C. less social capital but more social mobility. [35%]
- ☐ D. more social capital but less social mobility. [22%]

Correct

40% answered correctly

Explanation:

Social networks are informal and nonhierarchical **webs of interaction** between nodes, which are linked by ties. **Nodes** can either be individuals or organizations. **Ties** describe the **connections** between the nodes and are defined as strong or weak. **Weak ties** are loose/flimsy connections, such as those between acquaintances, whereas **strong ties** are more solid connections, such as those between family and close friends.

Social capital refers to a person's **networks** of people that can be converted into **economic gain**. Men's networks are larger and provide information about work-related topics, such as where there are job openings or promotion possibilities. Therefore, men's network connections confer more social capital because these connections can be more easily converted into economic gain.

Social mobility refers to the **movement** of individuals, groups, or families **between** or **within status categories** in society (eg, from middle class to upper class). Social mobility can be horizontal or vertical and is related to a multitude of other factors, such as education, job loss, marriage, and institutionalized discrimination. By providing more social capital (potential economic gain), men's networks also provide more social mobility.

(Choices A, C, and D) Compared to women's networks, men's social networks provide more (not less) social capital and more (not less) social mobility.

Educational objective:

Social networks are informal, nonhierarchical webs of nodes (eg, individuals) connected by ties, which can be weak (eg, acquaintances) or strong (eg, family). Social networks confer social capital through connections that can be converted into economic gain (eg, new job), which can improve one's social status, resulting in social mobility.

To investigate attributions related to exercise, an experimenter interviewed primary care physicians (PCPs) about their own exercise habits and their patients' reported exercise habits. The experimenter found that PCPs were more likely to attribute their own lack of exercise to factors such as being too busy, but were more likely to attribute their patients' lack of exercise to factors such as laziness. These results best illustrate the:

- ✔ ☒ A. actor-observer bias. [37%]
- ☐ B. experimenter bias.
- ☐ C. fundamental attribution error. [38%]
- ☐ D. self-serving bias. [23%]

Correct

37% answered correctly

Explanation:

Attributional biases are cognitive biases (common errors in thinking) that occur when people attempt to **explain** their own **behavior** or the behavior of someone else. Attributions can be **dispositional**, based on **internal** characteristics (eg, personality), or **situational**, based on **external** factors (eg, environment).

The **actor-observer bias** is an attributional bias that describes the tendency to attribute one's **own actions** to **external** factors but the actions of **others** to

internal factors. The physicians' tendency to make external attributions for their own lack of exercise (eg, "I'm too busy") while attributing their patients' lack of exercise to internal factors (eg, "they are lazy") best supports the actor-observer bias.

(Choice B) Experimenter bias occurs when researchers deliberately or inadvertently influence their study, often leading to results that confirm what the researcher was expecting. Experimenter bias is not a type of attributional bias, and it is not illustrated by the results.

(Choice C) The fundamental attribution error, an attributional bias, is the tendency to blame others' behavior on internal (eg, "they are lazy") instead of external factors. The fundamental attribution error fails to account for the finding regarding physicians' attributions for their *own behaviors*.

(Choice D) Self-serving bias is an attributional bias that occurs when individuals credit their successes to internal factors but blame their failures on external factors. The results do not provide information about attributions related to success.

Educational objective:

Attributional biases are common errors in thinking that occur when people attempt to explain behavior (their own or someone else's). The actor-observer bias occurs when individuals attribute their own behavior to external factors but attribute the behavior of others to internal factors.

Which of the following is the LEAST concerned with the role of nonverbal communication in influencing the social behavior of individuals?

- ☐ A. Elaboration likelihood model [23%]
- ☐ B. Dramaturgical perspective [14%]
- ☐ C. Symbolic interactionism [7%]
- ✓ ☒ D. Structural functionalism [54%]

Correct

54% answered correctly

Explanation:

Nonverbal communication involves all the **wordless cues** that convey **meaning** when exchanged between individuals. Cues include physical distance between face-to-face speakers, body language and other physical movements, facial expressions, and vocal modifications (eg, tone, volume, emphasis, inflection). Research suggests that social interaction is largely influenced by nonverbal communication.

Structural functionalism is a macro-level (large-scale) sociological perspective suggesting that all aspects of society work together to maintain dynamic equilibrium (societal balance). Structural functionalism is not concerned with micro-level (small-scale) interactions between individuals, so this theory would be the *least* concerned with how nonverbal communication influences the social behavior of individuals.

The elaboration likelihood model, dramaturgical perspective, and symbolic interactionism each deal with how individuals interact with and attempt to influence each other, partly through the use of nonverbal cues.

(Choice A) The elaboration likelihood model of persuasion proposes that when an individual is uninterested in a message, superficial factors (eg, an attractive celebrity spokesperson) might be most persuasive. Therefore, the elaboration likelihood model is concerned with how nonverbal cues can influence the behavior of individuals.

(Choices B and C) Symbolic interactionism is a micro-level sociological theory that suggests that people communicate using symbols (eg, hand gestures). Stemming from symbolic interactionism, the dramaturgical perspective proposes that individuals behave as actors, behaving in front of others in ways that align with social norms. Both approaches are concerned with how nonverbal cues influence the behavior of others.

Educational objective:

Nonverbal communication includes all the wordless cues meant to convey meaning to another individual, such as body language, hand gestures, facial expressions, and vocal inflections. Research suggests that nonverbal communication has an important impact on social interactions.

Identity and Social Interaction

A group of five health care professionals is presented with a complex system-based problem in a large hospital and asked to generate multiple possible solutions. Research on group processes suggests that:

- ☐ A. if group members get along, more options will be discussed and considered. [13%]
- ☐ B. the group is more likely to come up with an effective solution if there is a strong group leader. [8%]
- ✓ ☒ C. if group members start with similar opinions, they will support an option that is more extreme. [68%]
- ☐ D. on average, individuals working alone will produce fewer options than when working in a group. [8%]

Correct

68% answered correctly

Explanation:

Group polarization occurs when group members adopt a **more extreme** attitude or course of action **after group discussion**. Group polarization is more likely to occur if group members have similar opinions before group discussion. Group discussion strengthens and reconfirms individuals' opinions, resulting in an average viewpoint that is more extreme. Group polarization can occur in either direction (ie, extremely positive or extremely negative).

(Choice A) Groupthink occurs when a group arrives at an incorrect or irrational decision because group members value getting along and reaching a consensus more than they value critical evaluation of alternatives. Therefore, if group members get along, *fewer* (not more) options will be discussed and considered.

(Choice B) Groupthink is more likely to occur in groups that have strong, well-liked leaders. Groupthink results in irrational decision making because group members do not want to cause discord or thwart progress, so they do not speak up. Groupthink is more likely to produce *inaccurate or ineffective* (not effective) group decisions.

(Choice D) Social loafing occurs when an individual exerts less effort as a member of a

group than when alone. Individuals working alone tend to come up with *more* (not fewer) options than when working in a group, on average.

Educational objective:

Group polarization occurs when the views of individuals within a group become more extreme after discussion with like-minded members. Opinions can be polarized in either direction (extremely positive or extremely negative).
