

A study found that over time, compared to white immigrants, immigrants of color experience poorer health overall. The researchers hypothesized that these immigrants, while living in the United States, are confronted with implicit and explicit negative messages about their outsider status as both a racial "minority" and as "immigrants," which have a cumulative impact on health. This hypothesis is most related to which pair of factors?

- ✓ ☒ A. Intersectionality and racialization [39%]
- ☐ B. Cultural transmission and racialization [11%]
- ☐ C. Intersectionality and stereotype threat [37%]
- ☐ D. Cultural transmission and stereotype threat [11%]

Correct

39% answered correctly

Explanation:

Intersectionality describes how individuals hold **multiple, interconnected, marginalized** social **identities** (eg, gender, race, age) that **impact** their **lives, perspectives, and treatment** in society. In other words, the experience of more than one type of discrimination (eg, sexism, racism, ageism) has a *cumulative effect* on many individuals.

Racialization is the process by which one group **designates** another group with a racial **identity**, often based on shared group qualities, such as physical attributes (eg, skin pigmentation) or behaviors (eg, religious practices). The designating group has more social power (dominant group) and exerts social control over the designated group, which has less social power (subordinate group).

The hypothesis that implicit and explicit negative messages about outsider status as both a racial "minority" and an "immigrant" have a cumulative impact on health is related to *intersectionality* (cumulative effects of racial "minority" and "immigrant" statuses) and *racialization* (implicit and explicit messages about one's racial "minority" status).

(Choices B and D) Cultural transmission, which describes the passing of cultural information (eg, behaviors, beliefs, objects) from one generation to the next, is not related to the researchers' hypothesis.

(Choices C and D) Stereotype threat occurs when task performance suffers as a result of being made aware before the task of a negative stereotype about a group to which one belongs (eg, awareness of the stereotype "women are bad at math" before a math task hinders women's performance). The researchers' hypothesis is unrelated to negatively impacted *task performance*.

Educational objective:

Intersectionality describes how multiple, interconnected, marginalized social identities simultaneously impact individual's lives, perspectives, and treatment in society. Racialization is the process by which one group (the dominant group) designates another (a subordinate group) with a racial identity.
